March 22, 2011

Dear Colleague,

I am writing to tell you of our experience with the Exilis non-invasive skin tightening device that we received over 5 months ago. The response from our patient's has been overwhelming and the results have been consistent and especially good when the proper candidate is selected. I suppose the same can be said for any cosmetic procedure, but I emphasize this because the treatment belongs on a spectrum from skin care and injectibles on one end to surgery on the other. Almost any patient is a candidate for some form of skin tightening but there are those who are ideal for the Exilis. In my practice those are the pre-facelift and post facelift population. Patients in their late forties and early fifties, with initial signs of facial aging including jowling and jawline and neck skin laxity do remarkably well with this form of treatment and I have been using it to maintain my face and neck lift results. Patients who are 18-24 months out from face and neck lifting procedures often get some "stretch back" of the skin due to inelasticity. These patients also do extremely well with Exilis treatments and I hope that we can increase the longevity of the more invasive procedures by using non-invasive modalities.

I am convinced of the safety of the procedure and the reliability of the device after working with it for several months and several hundred treatment sessions. In fact we have been transporting it to our other office location once a week and have had no problems with set up or function. Patients feel the heat but 98% of them can tolerate high setting full treatment sessions without pain. This is important because adequate treatment parameters yield more consistent clinical results. The clinical support and training we received was excellent and personalized and we are thrilled with our decision to offer this treatment option to our patients.

Yours Truly,

Jon B. Turk, MD
